# Diastolic Heart Failure

## Clinical Definition

---

A clinical syndrome characterized by the symptoms and signs of HF, a preserved ejection fraction ( $\geq 50\%$ ), and abnormal diastolic function. Recently the most commonly used term is HFpEF.

# ↑ Stiffness in HFpEF

# Global CV Reserve Dysfunction in HFpEF

Borlaug BA et al JACC 2010;56:845

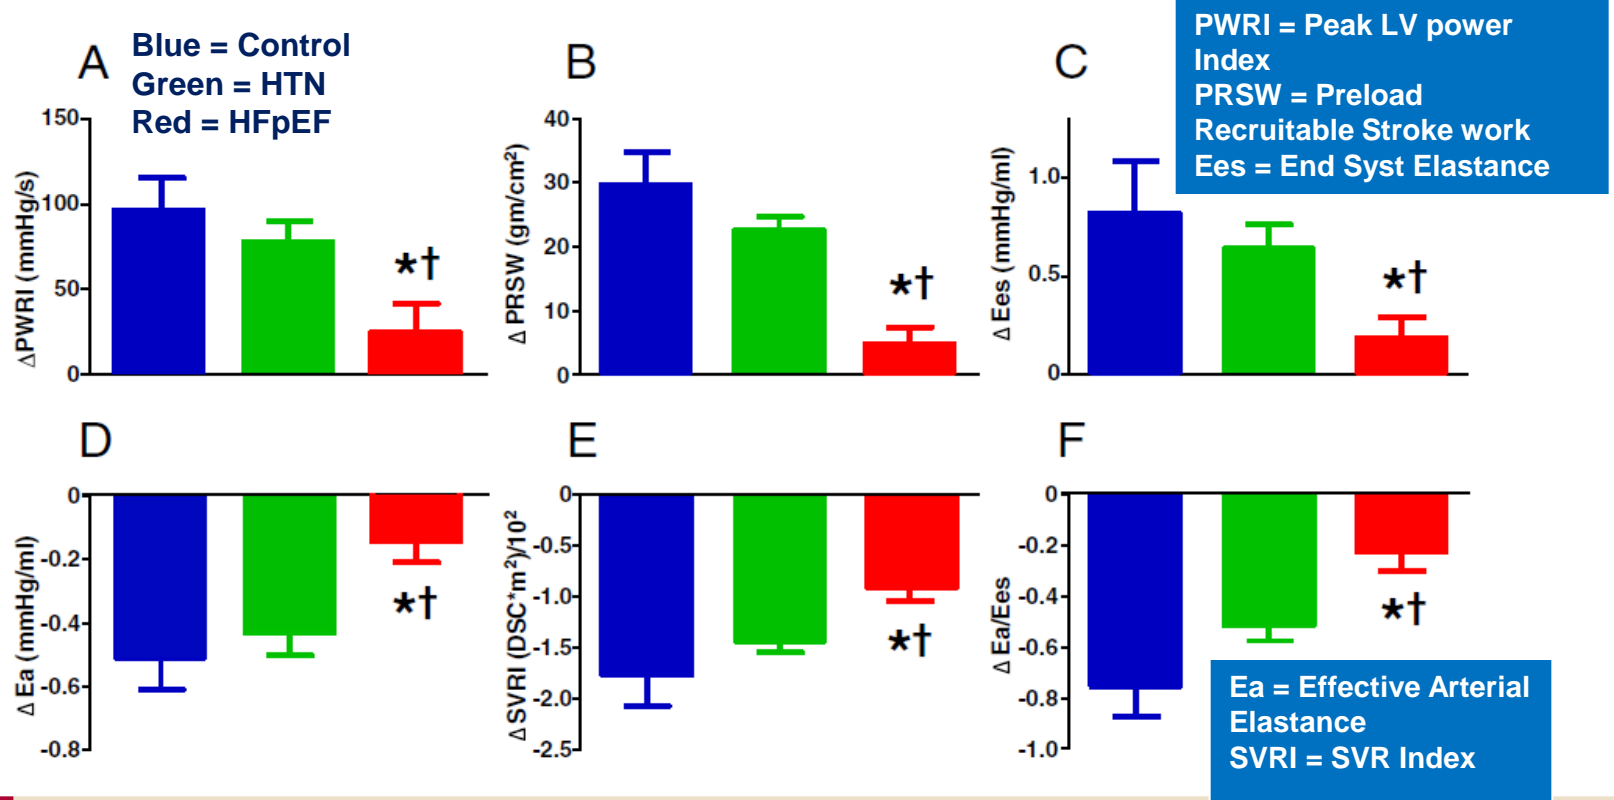

**Figure 1** Assessment of Endothelial Function

**PAT=Peripheral Arterial Tonometry**  
**RHI=Reactive Hyperemia Index**

(A) Increases in peripheral arterial tonometry (PAT) amplitude with reactive hyperemia are diminished in heart failure with preserved ejection fraction (HFpEF) patients (red line) and hypertensive subjects (green line) compared with control subjects (blue line), consistent with endothelial dysfunction. (B) Mean reactive hyperemia index (log RHI) is reduced in HFpEF subjects (red bar) and hypertensive subjects (green bar) compared with control (blue bar). (C) Compared with control, endothelial dysfunction (orange area) was more prevalent in HFpEF subjects (42%,  $p < 0.05$ ) and tended to be more common in hypertensive subjects (28%,  $p = 0.056$ ). Green area of bars indicates normal. \* $p < 0.05$  HFpEF versus control; † $p < 0.05$  hypertension versus control. CON = control; HTN = hypertension.

# Global CV Reserve Dysfunction in HFpEF

Borlaug BA et al JACC 2010;56:845

**Figure 2** Contractile, Vascular, and Coupling Reserve With Low-Level Exercise (20 W)

(A to C) Compared with both control subjects (blue bars) and hypertensive subjects (green bars), contractile reserve was blunted in heart failure with preserved ejection fraction (HFpEF) (red bars) at 20 W, evidenced by blunted increases in end-systolic elastance (Ees), pre-load recruitable stroke work (PRSW), and peak power index (PWRI). (D, E) Vasodilation (reduction in arterial elastance [Ea] and systemic vascular resistance index [SVRI]) was also impaired in HFpEF. (F) These deficits led to abnormal ventricular-arterial coupling responses (i.e., less reduction in Ea/Ees ratio) in HFpEF subjects compared with controls and hypertensive subjects. \*p < 0.05 versus hypertension; †p < 0.05 versus control (analysis of variance after Bonferroni).

# Vasodilation in HFrEF and HApEF

Schwarzenberg s et al JACC 2012;59:442

**Figure 2** Peripheral and Central Hemodynamic Changes With Nitroprusside

Nitroprusside caused greater blood pressure (BP) reduction in heart failure with preserved ejection fraction (HFpEF) (**black**) compared with heart failure with reduced ejection fraction (HFrEF) (**red**), whereas augmentation in stroke volume (SV) and cardiac output were greater in HFrEF compared with HFpEF. PCWP = pulmonary capillary wedge pressure; SBP = systolic blood pressure.

# Exercise intolerance in patients with HFpEF

Haykowski et al JACC 2011;58:265

Figure 3

Comparison of Change and Percentage of Change From Rest to 12 W, Rest to 25 W, and Rest to Peak Exercise in HFPEF Patients and HCs

End-diastolic volume (A1 and A2), end-systolic volume (B1 and B2), stroke volume (C1 and C2), and cardiac output (E1 and E2) adjusted for sex and body surface area. Heart rate (D1 and D2) adjusted for sex (\*p < 0.05, †p < 0.01). Solid bars = HFPEF patients; open bars = HCs. Abbreviations as in Figure 1.

*Rochester, Minnesota; and Singapore, Singapore*

- Objectives** This study sought to define the prevalence, severity, and significance of pulmonary hypertension (PH) in heart failure with preserved ejection fraction (HFpEF) in the general community.
- Background** Although HFpEF is known to cause PH, its development is highly variable. Community-based data are lacking, and the relative contribution of pulmonary venous versus pulmonary arterial hypertension (HTN) to PH in HFpEF is unknown. We hypothesized that PH would be a marker of symptomatic pulmonary congestion, distinguishing HFpEF from pre-clinical hypertensive heart disease.
- Methods** This community-based study of 244 HFpEF patients (age  $76 \pm 13$  years; 45% male) was followed up using Doppler echocardiography over 3 years. Control subjects were 719 adults with HTN without HF (age  $66 \pm 10$  years; 44% male). Pulmonary artery systolic pressure (PASP) was derived from the tricuspid regurgitation velocity and PH defined as PASP  $>35$  mm Hg. Pulmonary capillary wedge pressure (PCWP) was estimated from the ratio of early transmitral flow velocity to early mitral annular diastolic velocity.
- Results** In HFpEF, PH was present in 83% and the median (25th, 75th percentile) PASP was 48 (37, 56) mm Hg. PASP increased with PCWP ( $r = 0.21$ ;  $p < 0.007$ ). Adjusting for PCWP, PASP was higher in HFpEF than HTN ( $p < 0.001$ ). The PASP distinguished HFpEF from HTN with an area under the receiver-operating characteristic curve of 0.91 ( $p < 0.001$ ) and strongly predicted mortality in HFpEF (hazard ratio: 1.3 per 10 mm Hg;  $p < 0.001$ ).
- Conclusions** PH is highly prevalent and often severe in HFpEF. Although pulmonary venous HTN contributes to PH, it does not fully account for the severity of PH in HFpEF, suggesting that a component of pulmonary arterial HTN also contributes. The potent effect of PASP on mortality lends support for therapies aimed at pulmonary arterial HTN in HFpEF. # Exercise Hemodynamics for Early Diagnosis of HFpEF

## Exercise Hemodynamics Enhance Diagnosis of Early Heart Failure With Preserved Ejection Fraction

Barry A. Borlaug, MD; Rick A. Nishimura, MD; Paul Sorajja, MD;  
Carolyn S.P. Lam, MBBS; Margaret M. Redfield, MD

**Background**—When advanced, heart failure with preserved ejection fraction (HFpEF) is readily apparent. However, diagnosis of earlier disease may be challenging because exertional dyspnea is not specific for heart failure, and biomarkers and hemodynamic indicators of volume overload may be absent at rest.

**Methods and Results**—Patients with exertional dyspnea and ejection fraction  $>50\%$  were referred for hemodynamic catheterization. Those with no significant coronary disease, normal brain natriuretic peptide assay, and normal resting hemodynamics (mean pulmonary artery pressure  $<25$  mm Hg and pulmonary capillary wedge pressure [PCWP]  $<15$  mm Hg) ( $n=55$ ) underwent exercise study. The exercise PCWP was used to classify patients as having HFpEF (PCWP  $\geq 25$  mm Hg) ( $n=32$ ) or noncardiac dyspnea (PCWP  $<25$  mm Hg) ( $n=23$ ). At rest, patients with HFpEF had higher resting pulmonary artery pressure and PCWP, although all values fell within normal limits. Exercise-induced elevation in PCWP in HFpEF was confirmed by greater increases in left ventricular end-diastolic pressure and was associated with blunted increases in heart rate, systemic vasodilation, and cardiac output. Exercise-induced pulmonary hypertension was present in 88% of patients with HFpEF and was related principally to elevated PCWP, as pulmonary vascular resistances dropped similarly in both groups. Exercise PCWP and pulmonary artery systolic pressure were highly correlated. An exercise pulmonary artery systolic pressure  $\geq 45$  mm Hg identified HFpEF with 96% sensitivity and 95% specificity.

**Conclusions**—Euvolemic patients with exertional dyspnea, normal brain natriuretic peptide, and normal cardiac filling pressures at rest may have markedly abnormal hemodynamic responses during exercise, suggesting that chronic symptoms are related to heart failure. Earlier and more accurate diagnosis using exercise hemodynamics may allow better targeting of interventions to treat and prevent HFpEF progression. (*Circ Heart Fail.* 2010;3:588-595.)

# summary

---

- HFpEF is a syndrome which in addition to Impaired myocardial Relaxation is associated with endothelial dysfunction, impaired vasodilatory reserve, subtle systolic dysfunction, impaired systolic reserve, chronotropic incompetence, and pulmonary hypertension. All of these lead to symptoms of heart failure and worse prognosis.

# summary

---

- **Diagnosis usually relies on non invasive criteria but can be enhanced by hemodynamic assessment of resting LV filling pressure as well as hemodynamic response to exercise (hand grip), leg raising and fluid loading.**

# **Heart Failure with Preserved Ejection Fraction**

# RELAX – Sildenafil in HFpEF

Redfield MM et al , JAMA 2013;309:1268

- 216 stable out patients with HFpEF ( $\geq 50\%$ ).
- Elevated BNP or invasively measured LVEDP.
- Reduced exercise capacity.
- Randomized to placebo or sildenafil 20mg tid for 12 weeks followed by 60 mg tid for 12 weeks.
- Results : No change in Peak  $\text{VO}_2$ , (primary end point), 6 minutes walk, and clinical status.

# ALDO – DHF Trial

## Spironolactone in HFpEF

- 10 sites in Germany & Austria.
- 422 patients with HFpEF, NHAf class II-III.
- Echo evidence of LV diastolic dysfunction.
- Peak  $VO_2 < 25$  ml/Kg/min.
- Randomized to spironolactone 25 mg/d vs. placebo.
- Results: Sig. improvement in diastolic dysfunction, LV mass index and BNP level.
- No sig. change in peak  $VO_2$ , symptoms and QOL.
- Decrease in 6 min walk distance and GFR and an increase in serum potassium.

# Summary

- Recent studies involving the use of aldosterone antagonists and PDE5-I (Sildenafil) have been added to a long list of therapeutic interventions, effective in patients with HFrEF including ACE inhibitors, ARBs and beta blockers which have failed in patients with HFpEF.

# Heart Failure Practice Guideline

## Section 11 : HF with Preserved LVEF

- Careful attention to differential diagnosis because treatment may differ (C).
- Evaluation for ischemic heart disease (C).
- Aggressive BP management (C).
- Use of low sodium diet (C).

# Heart Failure Practice Guideline

## Section 11 : HF with Preserved LVEF

- Diuretics to patients with evidence of volume overload but avoid excessive diuresis to prevent orthostatic hypotension and WRF (C).
- ARBs (B) or ACE inhibitors (C) should be considered.
- Measures to restore and maintain NSR should be considered in patients with symptomatic atrial flutter or fibrillation (C).
