Background

- **Left ventricular mechanical dyssynchrony** assessed by phase analysis from gated SPECT myocardial perfusion imaging (MPI) has been studied in patients with left ventricular dysfunction with various clinical settings
- Recent data have indicated that **LV mechanical dyssynchrony** may be mandatory for prediction of **CRT** responses
- Aljaroudi et al reported on relation of LV dyssynchrony by phase analysis of gated SPECT images and cardiovascular events in heart failure patients with **ICD** (JNC 2010)

Background

- **LVMD** by Gated SPECT studies has been validated for measuring by phase analysis based on the first harmonic approximation.
- This technique performed with Emory Cardiac Toolbox software (SyncTool) is fully automated and processed data obtained during routine gated SPECT imaging.
- There are two parameters related with LV dyssynchrony: phase standard deviation (**PSD**) and histogram bandwidth (**PBW**).

Smooth Phase Map Save Phase Result

Aims

- **Assess LV dyssynchrony** by gated SPECT MPI in patients referred for evaluation by standard Tc-99m sestamibi MPI for ischemia, scar, myocardial viability, and LV function.
- Form a local normal-control database of phase analysis parameters.
- Examine the relationship between clinical and MPI parameters, including **LV dyssynchrony**, with cardiac events.
- Determine the predictive value of **LV dyssynchrony** for cardiac events.

Methods

- Between Jan 2010 and Dec 2011, in consecutive patients referred for Tc sestamibi gated SPECT MPI, phase analysis software for evaluation of **LVMD** was applied.
- **LVMD** was measured by phase standard deviation (PSD) and histogram bandwidth (PBW).

Methods

- Patients' characteristics, risk factors for CAD, SPECT MPI, phase analysis results, ECG, QRS width of baseline ECG and EF were analyzed.
- The patients were followed-up for cardiac events defined as: cardiac death, heart failure hospitalizations, life threatening arrhythmias

Results

- The cohort study included 873 consecutive patients and 787 were followed.
- At a median follow-up of 19.1 ± 5.7 months, 45 (5.7%) patients had at least one **cardiac event**
 - 26 cardiac death
 - 16 HF exacerbation-hospitalizations
 - 3 VT/VF

Limitations

- The study population, although being a consecutive cohort who referred for MPI, was consisted of a **higher percentage of patients with heart failure** who routinely referred for MPI for **viability** assessment. As such in centers where the referrals for MPI is mainly on ambulatory basis, the results might be different.

Conclusions

- Routine gated SPECT MPI with phase analysis is a useful tool to assess LV dyssynchrony
- Together with perfusion and function data, LV dyssynchrony as presented by **phase standard deviation** can predict cardiac outcome especially in patients with LV dysfunction as It is the only independent predictor for cardiac death.

- Thank you!!
